

### Exercise for Analysis of Algorithms

#### Exercise T4

If a flow diagram consists of  $n$  nodes and  $m$  edges, how many fundamental cycles do we get?

#### Solution:

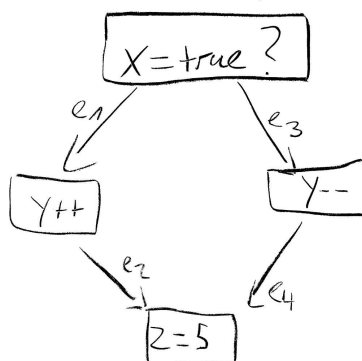

Any spanning tree of a graph on  $n$  nodes has to use exactly  $n - 1$  edges. that means that there are  $m - (n - 1)$  edges that are not part of the spanning tree. Since every edge not part of the spanning tree is part of exactly one fundamental cycle we get  $m - n + 1$  many fundamental cycles.

#### Exercise T5

Prove or disprove: In every flow diagram you can find a spanning tree such that all fundamental cycles contain only edges that are labeled with plus.

#### Solution:

Consider a part of a program that contains an if-else statement.

A spanning tree of that structure always has one edge not part of the tree, no matter what edge is selected, we always have to use the two edges of the other side in the opposite direction. So without loss of generality let  $e_1$  be the non tree edge,  $e_2$  the edge on the same side (either before or after  $e_1$ ) and  $e_3$  and  $e_4$  the two edges on the other side. We get

$$C_1 = e_1 + e_2 - e_3 - e_4$$

Which thereby disproves the conjecture.

### Exercise T6

In this exercise, we consider Prim's Algorithm, which computes a minimum spanning tree. The input to this algorithm is a graph  $G = (V, E)$ , a weight function on the edges  $w : E \rightarrow \mathbf{R}$  and a starting node  $r$ .

```

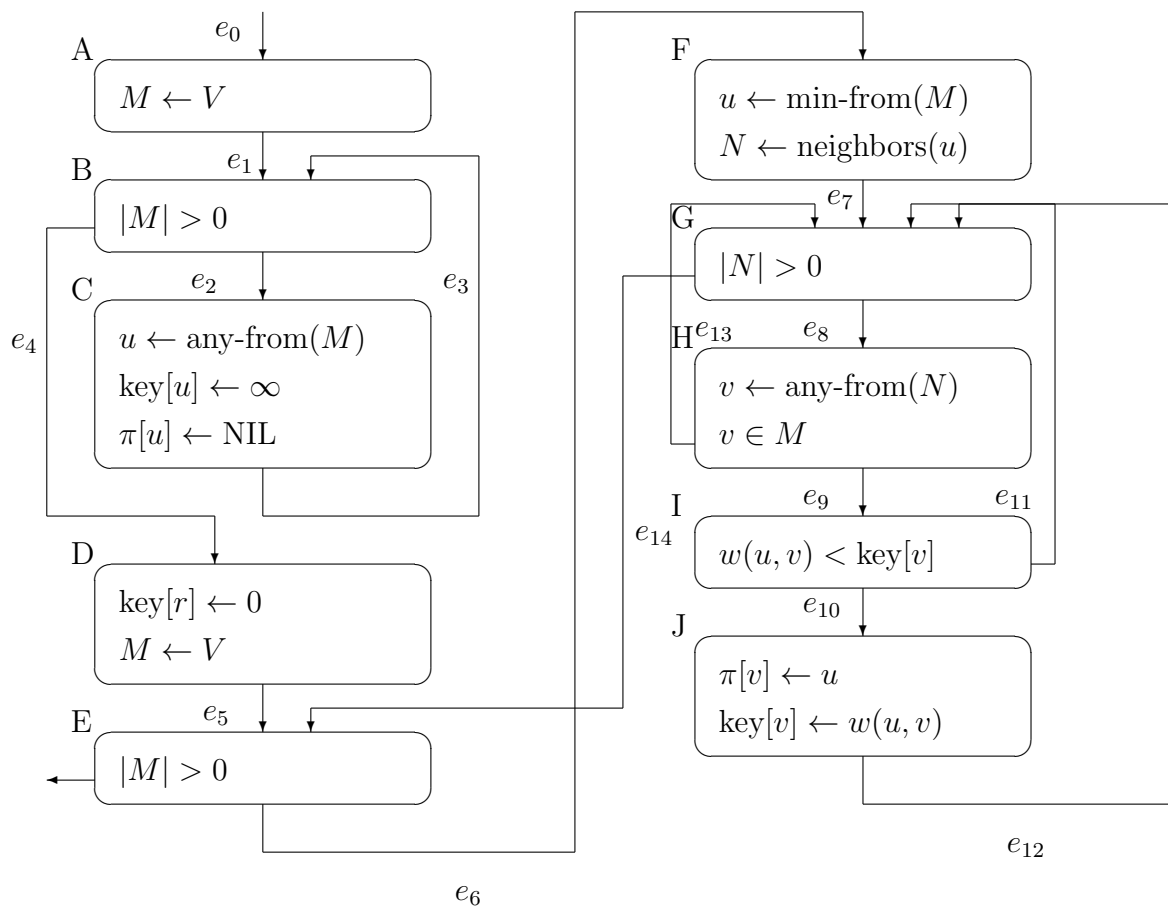

1  for each  $u \in V$  do
2       $key[u] \leftarrow \infty$ 
3       $\pi[u] \leftarrow \text{NIL}$ 
4   $key[r] \leftarrow 0$ 
5   $M \leftarrow V$ 
6  while ( $M \neq \emptyset$ ) do
7       $u \leftarrow \text{min-from}(M)$ 
8      for each  $v \in \text{neighbors}(u)$  do
9          if ( $v \in M \wedge (w(u, v) < key[v])$ ) then
10              $\pi[v] \leftarrow u$ 
11              $key[v] \leftarrow w(u, v)$ 

```

Construct the control flow graph, a spanning tree in the control flow graph, the fundamental cycles, a corresponding linear system of equations and a solution to this system.

### Solution:

The flow diagram is depicted below. The **for**-loops were changed, since the initializing and iteration condition must be separated.

We choose the spanning tree  $e_1, e_2, e_4, e_5, e_6, e_7, e_8, e_9, e_{10}$ . This yields the following fundamental cycles:

$$\begin{aligned} C_0 &= e_0 + e_1 + e_4 + e_5 \\ C_3 &= e_3 + e_2 \\ C_{11} &= e_{11} + e_8 + e_9 \\ C_{12} &= e_{12} + e_8 + e_9 + e_{10} \\ C_{13} &= e_{13} + e_8 \\ C_{14} &= e_{14} + e_6 + e_7 \end{aligned}$$

We now use standard linear algebra to find a good set of blocks whose number of visits we need to compute: By  $E_i, 0 \leq i \leq 14$ , we denote the number of times the program flow visits the edge  $e_i$ . With each fundamental cycle above we identify a vector  $C_i$ . Then the  $E_i$  can be written as a linear combination of the fundamental cycles, i.e.,

$$(C_0, C_3, C_{11}, C_{12}, C_{13}, C_{14}) \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \\ \lambda_4 \\ \lambda_5 \\ \lambda_6 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \\ \lambda_4 \\ \lambda_5 \\ \lambda_6 \end{pmatrix} = \begin{pmatrix} E_0 \\ E_1 \\ E_2 \\ E_3 \\ E_4 \\ E_5 \\ E_6 \\ E_7 \\ E_8 \\ E_9 \\ E_{10} \\ E_{11} \\ E_{12} \\ E_{13} \\ E_{14} \end{pmatrix}$$

for appropriate values of  $\lambda_1, \dots, \lambda_6$ . We select six independent rows and obtain the equation

$$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \\ \lambda_4 \\ \lambda_5 \\ \lambda_6 \end{pmatrix} = \begin{pmatrix} E_0 \\ E_2 \\ E_{11} \\ E_{12} \\ E_{13} \\ E_{14} \end{pmatrix} = \begin{pmatrix} 1 \\ C \\ I - J \\ J \\ H - I \\ G - H \end{pmatrix}.$$

This means, we only need to compute the values of  $C, G, H, I, J$  for a complete analysis ( $E_0 = 1$  is trivially known), and then all other values can be derived: We see that  $E_0 = E_1 = E_4 = E_5, E_2 = E_3, E_6 = E_7 = E_{14}, E_{10} = E_{12}$ . This implies  $A = 1, B = E_1 + E_3 = C + 1, D = E_4 = 1, E = E_5 + E_{14} = 1 + G - H, F = E_6 = G - H$ .

### Exercise H3

Consider the following program: The input to this program is an array  $a[0, \dots, n - 1]$  that contains  $n$  pairwise distinct integer keys in random order.

```

int sel_sort ( int a[], int n ) {
    for ( int i = 0; i < n; ++i ) {
        int min = i;
        for ( int j = i; j < n; ++j ) {
            if ( a[j] < a[min] ) {
                min = j;
            }
        }
        int temp = a[i];
        a[i] = a[min];
        a[min] = temp;
    }
}

```

- Explain how this program sorts the given array.
- Analyse how often each instruction of the program is executed on average depending on  $n$ .
- There is only one instruction whose analysis is not trivial. Which one is it?

Make a table for small values of  $n$  by hand that lists the results for this instruction. Compare the table entries with the results from your closed formula that you obtained in b).

### Solution:

The algorithm is, as indicated by the name, selection sort: it finds the minimal element of the yet-to-be-sorted part and appends it to the sorted part by exchange.

For part b), the outer loop is execute  $n$  times, therefore each statement not in the inner loop is executed that often. The if-statement is executed exactly  $\frac{n(n+1)}{2}$  times, which leaves the  $\text{min} = j$  statement.

The first comparison ( $j = i$  to  $i$ ) always fails, therefore the expected number of executions (cf. Problem 1-2) then is

$$\sum_{i=0}^{n-1} \sum_{j=i+1}^{n-1} \frac{1}{j-i+1} = \sum_{i=0}^{n-1} \sum_{j=1}^{n-i-1} \frac{1}{j+1} = \sum_{i=0}^{n-1} (H_{n-i} - 1) = (n+1)H_n - 2n.$$
