

Tree Decompositions

A **tree decomposition** of a graph G is a tree, whose nodes are called **bags**. Every **bag** is a set of nodes from G .

- I Any node and any edge from G is contained in at least one **bag**.
- I A node contained in two **bags** A, B must be contained in any bag between A and B .

Tree Decompositions

Tree Decompositions and Treewidth

The **width** of a tree decomposition is the **size of the largest bag minus 1**.

⇒ Here, the treewidth is 2.

Tree Decompositions and Treewidth

Alternative definition:

The **treewidth** of G is the minimum number of cops, needed to catch a robber in G , minus 1.

Tree Decompositions and Treewidth

Given a tree decomposition of G with width w , many optimization problems on G can be solved in time $c^w \cdot \text{poly}(n)$ using dynamic programming on the tree decomposition.

Many problems can be solved fast, if a tree decomposition of small width can be found.

General Result

Any problem with the following properties is fixed parameter tractable:

- I Let $G = (V, E)$ a planar graph and k a number. Question: Exists some $S \subseteq V$ of size k with a certain property (e.g. S is a vertex cover).
- I There is a constant c such that the distance between any node and S is bounded by c .
- I Given a tree decomposition of width w , the problem can be solved in $f(w)n^{O(1)}$ steps.

Special cases are Vertex Cover, Independent Set, and Dominating Set.

Proof Idea

- I Since any node is at most c steps away from a node in S , there is no path of length more than $2c|S|$.
- I Hence, the **diameter** is $O(k)$, if there exists some S of size k .
- I The treewidth of a planar graph with diameter d is at most $3d$ (without proof).
- I If the diameter is larger than $2ck$, the output is **no**.
- I Otherwise, we obtain a tree decomposition of width $6ck$ and can use it to solve the problem.

Dynamic Programming on a Tree Decomposition

Dynamic Programming on a Tree Decomposition

General approach:

- I The tree decomposition is transferred into a **rooted tree**: An arbitrary node becomes the root. Children point to their parents.
- I A **bag** represents the subgraph induced by its children.
- I For any **bag** a table is calculated, showing the optimal solutions for its subgraphs.
- I The children's tables are calculated first.

Extended Monadic Second Order Graph Theory

We introduce a new logic called **MS₂-logic**.

This logic contains variables for nodes, edges, sets of nodes, and sets of edges.

There are the quantifiers \exists and \forall and operators \wedge , \vee and \neg .

Furthermore, the following relations are included:

$$u \in U, d \in D, inc(d, u), adj(u, v), \cdot = \cdot$$

where u, v are node variables, d is an edge variable, U is a node set variable, and D is an edge set variable.

Extended Monadic Second Order Graph Theory

A graph can either satisfy a formula or not. This allows for a description of graph classes by formulas.

Example

Which graphs satisfy the following formula:

$$\exists u \exists v \exists w (adj(u, v) \wedge adj(u, w) \wedge adj(v, w))$$

Is there a formula describing **bipartite graphs** ?

Courcelle's Theorem

Theorem

Let \mathcal{G} be a graph class, described by a formula in MS_2 -logic.

The following problem is fixed parameter tractable:

Input: Graph G with treewidth k

Parameter: k

Question: Does G belong to \mathcal{G}

Proof

difficult. . .
